Reflection

1. If I was to say breakdown the https://isha.sadhguru.org/us/en website I would break it down first by saying the website or project itself is the overarching structure that holds modules or apps, configuration files, and a database. The modules or apps are reusable modules such as the login or articles or meditation courses. The configuration files manage project functions like global variables and interfacing between views and templates.
2. To deploy a basic Django application locally first I would create or locate the folder that I would like to create the Django application within. Then I would make sure my selected virtual environment was activated. I would also make sure Django was installed within my virtual environment. Then I would run the necessary command within the command line within the virtual environment and the selected folder location with the command "django-admin.exe startproject <project name>" I would then create a superuser with the command "python manage.py createsuperuser" To deploy I would run my migration with the command "py manage.py migrate" Then I would run the server locally to make sure everything was created and even check my superuser with the command "py manage.py runserver"
3. If I was using the Django admin site I would make sure I knew how to use CRUD operations on other users for my website or application. This would be helpful to give different permissions and access to different users. This will also be helpful in developing my data models and also just monitor administrative tasks.
